AGS APPLIED MATERIALS

ABSTRACT: A novel Mo-promoted Ce−Zr mixed oxide catalyst prepared by a homogeneous precipitation method was used for the selective catalytic reduction (SCR) of  $NO<sub>x</sub>$  with  $NH<sub>3</sub>$ . The optimal catalyst showed high  $NH<sub>3</sub>$ -SCR activity,  $SO_2/H_2O$  durability, and thermal stability under test conditions. The addition of Mo inhibited growth of the  $CeO<sub>2</sub>$  particle size, improved the redox ability, and increased the amount of surface acidity, especially the Lewis acidity, all of which were favorable for the excellent  $NH<sub>3</sub>$ -SCR performance. It is believed that the catalyst is promising for the removal of NO<sup>x</sup> from diesel engine exhaust.

#### 1. INTRODUCTION

Nitrogen oxides  $(NO<sub>x</sub>)$  emitted from stationary and mobile sources have been major atmospheric pollutants. The selective catalytic reduction (SCR) of  $NO<sub>x</sub>$  with  $NH<sub>3</sub>$  or urea has been extensively studied as one of the most effective methods to remove  $\overrightarrow{NO}_{x}$ , and the most widely used commercial catalyst is  $V_2O_5-WO_3$ /Ti $O_2$ .<sup>[1](#page-7-0)-[4](#page-7-0)</sup> However, there are still some inevitable disadvantages with this catalyst system, such as the toxicity of vanadium pentoxide, narrow operation temperature window, and high conversion of  $SO_2$  to  $SO_3$  at high temperature.<sup>[5](#page-7-0)</sup> Therefore, it is desirable to develop a novel  $NH<sub>3</sub>$ -SCR catalyst that can substitute for the conventional V-based catalyst in recent years.

Cerium oxide  $(CeO<sub>2</sub>)$  as one of the most abundant rare-earth oxides has attracted much interest over the past decades in many catalytic reactions such as carbon monoxide oxidation, water−gas shift, nitric oxide reduction, and reforming reactions.<sup>[6](#page-8-0)−[8](#page-8-0)</sup> However, pure CeO<sub>2</sub> shows poor thermal stability and is susceptible sintering at high temperature.<sup>[9](#page-8-0)</sup> It has been reported that the addition of  $ZrO<sub>2</sub>$  to  $CeO<sub>2</sub>$  leads to improvement in the oxygen storage capacity and thermal stability.[10,11](#page-8-0) Ce−Zr mixed oxide combines the highly refractory property of  $ZrO<sub>2</sub>$  with the oxygen storage capacity of CeO<sub>2</sub>, which can be used as a catalyst or support for  $NH_{3-}$ SCR of  $NO<sub>x</sub>$ . It was found that nickel and sulfate modification increased the strength of Lewis acid sites and enhanced the NH<sub>3</sub> adsorption capacity, all of which were beneficial for improvement of the activity and selectivity of  $Ce-Zr$  catalyst.<sup>[12](#page-8-0)</sup> It was also believed that NiO on the  $CeO<sub>2</sub>$  nanorods played an important role for enhancement of the  $NH<sub>3</sub>$ -SCR activity because of the higher concentration of  $Ce^{3+}$ , larger amount of active  $O_{\alpha}$  lower amount of energy required for oxygen vacancy

distortion, and strong interaction between NO and  $\mathrm{NH}_3.^{13}$  $\mathrm{NH}_3.^{13}$  $\mathrm{NH}_3.^{13}$  The experimental and kinetic model results indicated that the  $MnO<sub>x</sub>(0.6)/Ce<sub>0.5</sub>Zr<sub>0.5</sub>O<sub>2</sub>$  catalyst showed high NO conversion and  $N<sub>2</sub>$  selectivity at low temperatures, and the apparent activation energy of the NH<sub>3</sub>-SCR reaction on  $MnO<sub>x</sub>(0.6)$ /  $Ce_{0.5}Zr_{0.5}O_2$  (18 kJ/mol) was lower than that on  $MnO_x/TiO_2$  $(38 \text{ kJ/mol})$ .<sup>[14](#page-8-0)</sup> A WO<sub>3</sub>/CeO<sub>2</sub>−ZrO<sub>2</sub> catalyst annealed in air at 800 °C for 1 h still showed high NH<sub>3</sub>-SCR activity.<sup>[15](#page-8-0)</sup> The three-dimensional ordered macroporous (3DOM)  $Ce_{0.75}Zr_{0.2}M_{0.05}O_{2-\delta}$  (M = Fe, Mn, Co) synthesized by a colloidal template method also exhibited good activity for  $NH_{3}$ -SCR of  $NO<sub>x</sub>$ ; the characterization results showed that the dopants were effectively doped into the Ce−Zr oxide solid solution and a strong synergistic effect existed between the dopants and Ce−Zr oxide, all of which were beneficial for improvement of the  $NH<sub>3</sub>$ -SCR activity.<sup>[16](#page-8-0)</sup> It was also found that the morphology of  $CeZrO_x$  had a remarkable effect on the performance of the MnO<sub>x</sub>/CeO<sub>2</sub>−ZrO<sub>2</sub> catalyst for the NH<sub>3</sub>-SCR reaction, and  $MnO_x/CeO_2-ZrO_2$  nanorods showed activity superior to that of nanotubes and nanopolyhedra.<sup>[17](#page-8-0)</sup>  $Ce_{0.75}Zr_{0.25}O_2 - PO_4^{3-}$  catalyst prepared by impregnating phosphates on  $\mathrm{Ce_{0.75}Zr_{0.25}O_2}$  still presented high SCR activity at 300−400 °C after hydrothermal aging at 760 °C for 48 h, which might result from the fact that phosphates improved NH<sub>3</sub> adsorption and suppressed the unselective oxidation of NH<sub>3</sub> at high temperatures.<sup>[18](#page-8-0)</sup> Although catalysts containing  $CeO<sub>2</sub>-ZrO<sub>2</sub>$  oxide, such as  $WO<sub>3</sub>/CeO<sub>2</sub>-ZrO<sub>2</sub><sup>15</sup>$ , MnO<sub>x</sub>/  $Ce_{0.5}Zr_{0.5}O_2^{-14}$ ,  $Ce_{0.75}Zr_{0.25}O_2 - PO_4^{-3}$  and Ni-modified  $Ce-Zr$ 

Received: January 21, 2015 Accepted: April 20, 2015 Published: April 20, 2015

oxide,<sup>[18](#page-8-0)</sup> have been used toward NH<sub>3</sub>-SCR of NO in recent years, the promotional effect of Mo addition on the NH<sub>3</sub>-SCR activity over  $CeO<sub>2</sub>-ZrO<sub>2</sub>$  and the thermal stability of  $CeMo<sub>0</sub> \times Zr<sub>2</sub>O<sub>x</sub>$  catalyst have never been investigated in recent publications. In addition,  $MoO<sub>3</sub>$  is widely used as a stabilizer and a promoter to improve the activity, mechanical, and structural properties of a  $V_2O_5/TiO_2$  catalyst for  $NH_3$ -SCR prcocess.<sup>[19](#page-8-0)–[21](#page-8-0)</sup> It was also found that the addition of MoO<sub>3</sub> promoted the adsorption and activation of NH<sub>3</sub>, which was conducive to improvement of the  $NH<sub>3</sub>-SCR$  activity of a  $MoO<sub>3</sub>$ -doped Ce/TiO<sub>2</sub> catalyst.<sup>[22](#page-8-0)</sup>

In order to take full advantage of the high NH<sub>3</sub>-SCR activity and thermal stability of Ce−Zr mixed oxide and promoting effect of  $MoO<sub>3</sub>$ , in the present work, a series of novel Mopromoted Ce−Zr catalysts was prepared by a homogeneous precipitation method and were applied to  $NH<sub>3</sub>$ -SCR of NO<sub>x</sub>. The catalyst showed high SCR activity,  $SO_2/H_2O$  durability, and thermal stability under test conditions. The structure, redox ability, and acidity of the catalyst were characterized using different techniques. The promotional effect of Mo species and the NH3-SCR reaction mechanism over the catalyst were fully discussed. The catalyst is quite promising for  $NO<sub>x</sub>$  emission control from diesel engine exhaust.

#### 2. EXPERIMENTAL SECTION

2.1. Catalyst Preparation and Activity Test. The catalysts were prepared by a novel and facile homogeneous precipitation method using urea as the precipitator.<sup>[23](#page-8-0)</sup> All chemicals used were of analytical grade. The aqueous solution of  $Ce(NO<sub>3</sub>)<sub>3</sub>·6H<sub>2</sub>O$ ,  $Zr(NO<sub>3</sub>)<sub>4</sub>·5H<sub>2</sub>O$ , and  $(NH_4)_{6}M_0$ <sub>7</sub>O<sub>24</sub>·4H<sub>2</sub>O was mixed with the required molar ratio. An excessive urea aqueous solution was then added to the mixed solution. The solution was heated to 90 °C and continuously stirred for 12 h. The pH variation of the mixed solution during the homogeneous precipitation process is shown in Figure S1 in the [Supporting Information](#page-7-0) (SI). The initial pH of the mixed solution, which was measured by a pH meter (Sartorius PB-10), was about 1.0 because of hydrolysis of the precursors. However, as the preparation time increased from 1.0 to 4.0 h, a substantial amount of precipitate was formed and the pH was greatly increased from 1.0 to 7.0 probably because of the decomposition of urea. After filtration and washing with deionized water, the resulting precipitate was dried at 100 °C overnight and subsequently calcined at 500 °C for 3 h in air. The bulk molar ratios of Ce:Mo:Zr in the CeMo<sub>a</sub>Zr<sub>2</sub>O<sub>x</sub> series of catalysts were analyzed by an inductively coupled plasma instrument (OPTMIA 2000DV). As shown in Table S1 in the [SI,](#page-7-0) the actual proportions of Ce:Mo:Zr in the bulk were not consistent with the designed ones, indicating that not all of the ions precipitated in the process of homogeneous precipitation. In addition, the distribution of Zr, Ce, and Mo derived from scanning electron microscopy−energy-dispersive Xray (SEM−EDX; Hitachi S-3000N) over CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> catalyst prepared by homogeneous precipitation was presented in Figure S2 in the [SI.](#page-7-0) Zr exhibited a slightly poor dispersion; however, the Ce and Mo species were homogeneously dispersed on the surface of the catalyst. The catalysts were also calcined at desired temperatures (500, 550, 600, 650, 700, and 750 °C) for 8 h to test the thermal stability. In addition, the CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> catalysts were also hydrothermally aged at 700 and 760 °C for 48 h to evaluate the hydrothermal stability. The calcined samples were crushed and sieved to 40−60 mesh for the activity test. The catalysts were denoted as  $CeMo<sub>a</sub>Zr<sub>b</sub>O<sub>x</sub>$ , where a (a = 0, 0.1, 0.5, 1.0, 1.5) represented the molar ratio of Mo:Ce and  $b$  ( $b =$ 0.5, 1.0, 2.0, 4.0) indicated the molar ratio of Zr:Ce. The  $CeMo_{0.5}Zr_2O_x$  catalysts calcined at different temperatures for 8 h were denoted as  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_{x}$ -t, where t represented the calcination temperature in degrees Celsius. For comparison, a conventional  $V_2O_5$ –WO<sub>3</sub>/TiO<sub>2</sub> catalyst with 3 wt % (or 1 wt %)  $V_2O_5$  and 10 wt % WO<sub>3</sub> was also prepared using the conventional impregnation method.  $NH_4VO_3$  and  $(NH_4)_{10}W_{12}O_{41}$  were used as sources of V and W,

respectively. After impregnation, the excess  $H_2O$  was removed in a rotary evaporator at 60 °C. The sample was dried at 100 °C overnight and subsequently calcined at desired temperatures for 8 h in air.

The NH<sub>3</sub>-SCR activity tests were carried out in a fixed-bed quartz tube reactor at atmospheric pressure. The weights of the catalysts employed were 1.10 g of  $CeZr<sub>2</sub>O<sub>x</sub>$ , 0.95 g of  $CeMo<sub>0.1</sub>Zr<sub>2</sub>O<sub>x</sub>$ , 0.75 g of CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub>, 0.67 g of CeMo<sub>1.0</sub>Zr<sub>2</sub>O<sub>x</sub>, and 0.56 g of CeMo<sub>1.5</sub>Zr<sub>2</sub>O<sub>x</sub> to maintain the gas hourly space velocity (GHSV) at 50000 h<sup>-1</sup> various catalysts. The reaction gas contained 500 ppm of NO (or  $[NO] = 250$  ppm;  $[NO<sub>2</sub>] = 250$  ppm), 500 ppm of NH<sub>3</sub>, 5 vol % O<sub>2</sub>,  $N_2$  balance, and 500 mL/min flow rate. Furthermore, 5 vol %  $H_2O$  or 100 ppm of  $SO_2$  (or 500 ppm of  $SO_2$ ) was introduced to the reaction gas to test the poisoning effect of  $H_2O/SO_2$  on NO<sub>x</sub> conversion over the  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_x$  catalyst. The effluent gas was continuously analyzed by a Fourier transform infrared (FTIR) spectrometer (Nicolet Nexus 670) equipped with a heated, low-volume multiple-path gas cell (2 m). The FTIR spectra were collected after 1 h when the SCR reaction reached a steady state.  $NO_x$  conversion and  $N_2$  selectivity were calculated as follows:

NO<sub>x</sub> conversion = 
$$
\left(1 - \frac{[NO]_{out} + [NO_2]_{out}}{[NO]_{in} + [NO_2]_{in}}\right) \times 100\%
$$
  
\nN<sub>2</sub> selectivity =  $\frac{[NO]_{in} + [NH_3]_{in} - [NO_2]_{out} - 2[N_2O]_{out}}{[NO]_{in} + [NH_3]_{in}}$   
\n× 100%

**2.2. Characterization.** The N<sub>2</sub> adsorption–desorption isotherms over catalysts were obtained at 77 K using a Quantachrome Autosorb-1C instrument. Prior to  $N_2$  physisorption, all samples were degassed in a vacuum at 300 °C for 5 h. The surface areas were determined by a Brunauer−Emmett−Teller (BET) equation in the 0.05−0.35 partial pressure range. Pore volumes were determined by the Barrett− Joyner−Halenda (BJH) method from the desorption branches of the isotherms.

Powder X-ray diffraction (XRD) measurements of the catalysts were carried out on a computerized PANalytical X'Pert Pro diffractometer with Cu K $\alpha$  ( $\lambda$  = 0.15406 nm) radiation. The data of 2 $\theta$  from 20 to 80° were collected at 8°/min with a step size of 0.07°.

Visible Raman spectra of the catalysts were collected at room temperature on a Spex 1877 D Triplemate spectrograph with a spectral resolution of 2 cm<sup>−</sup><sup>1</sup> . A 532 nm diode-pumped solid-state semiconductor laser was used as the excitation source with a power output of 30 mW. The time for recording each spectrum was 10 s.

The  $H_2$ -TPR (temperature-programmed reduction) experiments were carried out on a Micromeritics AutoChem 2920 chemisorption analyzer. In a typical measurement, 100 mg of the catalyst was first pretreated in a flow of 20 vol %  $O_2/N_2$  (50 mL/min) at 400 °C for 0.5 h and then cooled to the room temperature (30 °C) followed by Ar purging for 0.5 h. Then the temperature was linearly raised at 10 °C/ min from 30 to 700 °C in a flow of 10 vol %  $H_2/Ar$  (30 mL/min).  $H_2$ consumption was monitored by a thermal conductivity detector.

NH3-TPD (temperature-programmed decomposition) together with NO-TPD was also conducted on a Micromeritics AutoChem 2920 chemisorption analyzer, equipped with a quadrupole mass spectrometer (MKS Cirrus) to monitor the signals of  $NH<sub>3</sub>$  ( $m/z$  17) and NO  $(m/z 30)$ . Prior to TPD experiments, the 100 mg samples were pretreated at 400 °C in a flow of 20 vol %  $O_2/N$ , for 0.5 h and cooled to room temperature. Then the samples were exposed to a flow of NH<sub>3</sub> or NO +  $O_2$  for 1.0 h. Finally, the temperature was raised to 600 °C in an Ar flow at the rate of 10 °C/min.

The in situ diffuse-reflectance infrared Fourier transform spectroscopy (DRIFTS) experiments were carried out on an FTIR spectrometer (Nicolet Nexus 670) equipped with a smart collector and an MCT/A detector cooled by liquid nitrogen. Prior to each experiment, the sample was pretreated at 400 °C for 0.5 h in 20 vol %  $O_2/N_2$  and then cooled to 200 °C. The background spectrum was collected in flowing  $N_2$  and automatically subtracted from the sample spectrum. The reaction conditions were as follows: 500 ppm of  $NH<sub>3</sub>$ ,

# <span id="page-2-0"></span>ACS Applied Materials & Interfaces **Research Article** Research Article

500 ppm of NO, 5 vol %  $O_2$ , N<sub>2</sub> balance, and 200 mL/min flow rate. All spectra were recorded by accumulating 100 scans with a resolution of  $4 \text{ cm}^{-1}$ . .

## 3. RESULTS AND DISCUSSION

3.1.  $NH<sub>3</sub>-SCR$  Activity. Prior to investigation of the CeMo<sub>a</sub> $Zr_bO_x$  catalyst, the effect of the Ce:Zr molar ratio on the SCR activity over the CeZrO<sub>x</sub> series of catalysts was systematically investigated, and the results are illustrated in Figure S3 in the [SI.](#page-7-0) It was found that the  $CeZr<sub>2</sub>O<sub>x</sub>$  catalyst, with a Ce:Zr molar ratio of 1:2, showed the best  $NO<sub>x</sub>$  conversion. Therefore, in the later work, the Ce:Zr molar ratio was fixed at 1:2. Figure 1 shows the  $NO<sub>x</sub>$  conversion and  $N<sub>2</sub>$  selectivity as a

Figure 1. NO<sub>x</sub> conversion and N<sub>2</sub> selectivity (inserted) in the NH<sub>3</sub>-SCR reaction as a function of the temperature over pure  $MoO<sub>3</sub>$  and CeMo<sub>a</sub>Zr<sub>2</sub>O<sub>x</sub> ( $a = 0, 0.1, 0.5, 1.0, 1.5$ ) catalysts. Reaction conditions:  $[NO] = [NH<sub>3</sub>] = 500$  ppm,  $[O<sub>2</sub>] = 5$  vol %, and GHSV = 50000 h<sup>-1</sup>. .

function of the temperature in the  $NH<sub>3</sub>$ -SCR reaction over pure MoO<sub>3</sub> and CeMo<sub>a</sub> $Zr_2O_x$  catalysts under a GHSV of 50000 h<sup>-1</sup>. .  $CeZr<sub>2</sub>O<sub>x</sub>$  exhibited a narrow operation temperature window, and the maximum  $NO_x$  conversion was only 90% at 350 °C. However, the addition of a small amount of Mo ( $Mo:Ce =$ 0.1:1) to  $CeZr_2O_x$  led to an obvious enhancement of the NO<sub>x</sub> conversion, implying that the coexistence of Mo and  $CeZr<sub>2</sub>O<sub>x</sub>$ species was very important for promotion of the SCR activity. CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> with a molar ratio of Mo:Ce = 0.5:1 showed the best  $NH_{3}$ -SCR activity and the widest operation temperature window, over which 100% of  $NO<sub>x</sub>$  conversion was obtained in a wide temperature range (250−400 °C). Further increasing the Mo:Ce molar ratios to 1:1 and 1.5:1 resulted in a decline of the  $NO<sub>x</sub>$  conversion at both low and high temperatures, which was probably due to the decrease of active Ce sites on the catalyst surface. Similar results were also proposed by Shan et al. $24$  and Li et al.<sup>[25](#page-8-0)</sup> when investigating the  $CeO<sub>2</sub>–WO<sub>3</sub>$  and  $CeO<sub>2</sub>–$  $MoO<sub>3</sub>$  catalysts. Pure  $MoO<sub>3</sub>$  showed negligible activity in the whole temperature range, indicating that the Mo species played the role of only the catalyst promoter rather than the active center for the  $NH<sub>3</sub>-SCR$  reaction. Although the addition of MoO<sub>3</sub> to the Ce−Zr catalyst could decrease the N<sub>2</sub> selectivity slightly owing to the production of  $N_2O$ , the  $N_2$  selectivity over CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> was still more than 80% below 400 °C. The NH<sub>3</sub>-SCR results show that some synergistic effects possibly exist between Mo and Ce−Zr species, which will be discussed later in this work.

In addition, the catalytic activity over  $\text{CeMo}_{0.5}\text{Zr}_{b}\text{O}_{x}$  with various Zr:Ce molar ratios is presented in Figure S4 in the [SI](#page-7-0). It was obvious that the NO<sub>x</sub> conversions over CeMo<sub>0.5</sub> $Zr_1O_x$  and  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_{x}$  were similar and higher than those over  $CeMo<sub>0.5</sub>Zr<sub>0.5</sub>O<sub>x</sub>$  and  $CeMo<sub>0.5</sub>Zr<sub>4</sub>O<sub>x</sub>$  below 300 °C. However,  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_x$  showed better NH<sub>3</sub>-SCR activity than Ce- $Mo<sub>0</sub> Zr<sub>1</sub>O<sub>x</sub>$  above 350 °C. Therefore, in the following studies,  $CeMo<sub>05</sub>Zr<sub>2</sub>O<sub>x</sub>$  was chosen to investigate the "fast SCR" effect and  $SO_2/H_2O$  resistance together with the thermal durability of the Mo-containing catalyst.

It was clear that when  $NO_2 (NO_2:NO = 1:1)$  was introduced to the reaction gas, the NO<sub>x</sub> conversion over  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_x$  at low temperatures was greatly improved because of the "fast SCR" effect and the NO<sub>x</sub> conversion was as high as 100% in a wide temperature range from 150 to 400 °C; see Figure S5 in the [SI](#page-7-0). Therefore, in practical applications, the diesel oxidation catalyst usually is placed in the upstream of the SCR catalyst to convert some  $NO$  to  $NO<sub>2</sub>$ , which has a significant advantage on  $NO<sub>x</sub>$  removal. To better evaluate the performance of the  $CeMo_{0.5}Zr_2O_x$  catalyst, the NH<sub>3</sub>-SCR activity over the commercial V<sub>2</sub>O<sub>5</sub>(1)–WO<sub>3</sub>(10)/TiO<sub>2</sub> catalyst was also con-ducted and the results are shown in Figure S6 in the [SI](#page-7-0).  $NO<sub>x</sub>$ conversion over the CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> catalyst was higher than that over  $V_2O_5(1)-WO_3(10)/TiO_2$  even though the CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> sample exhibited a relatively low  $N_2$  selectivity at 400 and 450  $^{\circ}C$ .

3.2. Effect of  $SO_2$  and  $H_2O$ . The combustion exhaust often contains some  $SO_2$  and  $H_2O$  vapor in the practical application, which may lead to deactivation of the SCR catalyst.<sup>[26](#page-8-0)</sup> Therefore, it is important to investigate the effect of  $SO<sub>2</sub>$  and  $H<sub>2</sub>O$  on the SCR activity. In this work, we studied the effect of 100 ppm of  $SO_2$  and 5 vol %  $H_2O$  on the  $NO_x$  conversion over  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_x$  at 250 °C under a GHSV of 50000 h<sup>-1</sup>. As shown in Figure 2A, the introduction of 100 ppm of  $SO<sub>2</sub>$  into

Figure 2. Effect of SO<sub>2</sub> (A), H<sub>2</sub>O (B), and SO<sub>2</sub> + H<sub>2</sub>O (C) on the SCR activity over the  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_x$  catalyst at 250 °C. Reaction conditions:  $[NO] = [NH<sub>3</sub>] = 500$  ppm,  $[O<sub>2</sub>] = 5$  vol %,  $[SO<sub>2</sub>] = 100$ ppm,  $[H_2O] = 5$  vol %, and GHSV = 50000 h<sup>-1</sup>. .

the reaction atmosphere did not result in any decrease of the  $NO<sub>x</sub>$  conversion for the first 14 h. With the time increasing, the  $NO<sub>x</sub>$  conversion showed a slow decrease, which might be associated with the deposition of ammonium sulfate/bisulfate on the surface and blockage of the active sites. However, the conversion was still more than 90% during the measured period. The result in Figure 2B showed that when 5 vol %  $H_2O$ was added to the feed stream, the  $NO<sub>x</sub>$  conversion dramatically decreased from the initial 100% to 40% in the first 2 h and then

# ACS Applied Materials & Interfaces **Research Article** Research Article

recovered to 100%. It was believed that the deactivation effect of  $H<sub>2</sub>O$  on the activity over catalysts required a long time to achieve steady state. Therefore, when  $H<sub>2</sub>O$  vapor was first added into the reaction atmosphere, because of the competitive adsorption between  $H_2O$  and  $NH<sub>3</sub>/NO$  over the catalyst, a large amount of  $H<sub>2</sub>O$  was adsorbed on the active sites where the NH3/NO adsorbed and activated, leading to a decline of the NO<sub>x</sub> conversion. However, when the reaction reached steady state 2 h later, the desorption of excess  $H_2O$  adsorbed on the catalyst made it possible for adsorption and activation of NH3/NO on the active sites, which was responsible for the increase of the  $NO<sub>x</sub>$  conversion. As presented in Figure [2C](#page-2-0), when both 100 ppm of  $SO_2$  and 5 vol %  $H_2O$  were introduced, the  $NO<sub>x</sub>$  conversion also showed a relatively significant decrease to 35% and then maintained nearly 50%; after the  $SO<sub>2</sub>$  and  $H<sub>2</sub>O$  inlets were cut off, the activity was rapidly restored to 90%. In short summary,  $SO_2$  or  $H_2O$  alone just showed a negligible influence on the SCR activity; the coexistence of  $SO_2$  and  $H_2O$  decreased the conversion significantly, indicating that some synergistic inhibition effect between  $SO_2$  and  $H_2O$  was present on the SCR activity; however, the effect was reversible to a certain extent. It was believed that when both  $SO<sub>2</sub>$  and  $H<sub>2</sub>O$  were introduced to the reaction atmosphere, the deactivation effect might be not only related to the competitive adsorption between  $H_2O$  and  $NH<sub>3</sub>/$  $NO<sub>x</sub>$  but also associated with the formation of ammonium sulfate together with high thermally stable  $Ce(SO<sub>4</sub>)<sub>2</sub>$ /  $Ce<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>$  on the active sites because of  $SO<sub>2</sub>$ , which suggested that both  $H_2O$  and  $SO_2$  could inhibit the adsorption and activation of  $NH_3/NO_x$  on the active sites, leading to an obvious decline of the  $NO<sub>x</sub>$  conversion.

The reaction temperature had a great impact on the performance of the SCR catalyst. Therefore, the  $SO_2/H_2O$ resistance of the CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> catalyst was also conducted at 400 °C. As shown in Figure S7A in the [SI,](#page-7-0) the  $NO_x$  conversion still remained 100% after the introduction of 100 ppm of  $SO<sub>2</sub>$  at 400 °C for 48 h, which was higher than that at 250 °C in Figure [2](#page-2-0)A. The results indicated that the  $SO<sub>2</sub>$  tolerance was improved as the reaction temperature increased from 250 to 400 °C. As presented in Figure S7B in the [SI,](#page-7-0)  $5\%$  H<sub>2</sub>O alone has an insignificant effect on the SCR activity over the CeMo<sub>0.5</sub> $Zr_2O_x$ catalyst at 400  $^{\circ}$ C and NO<sub>x</sub> conversion was almost 100%. The results in Figure S7C in the [SI](#page-7-0) demonstrated that when both  $SO_2$  and H<sub>2</sub>O were introduced to the reaction gas, the NO<sub>x</sub> conversion exhibited a trend similar to that in Figure [2C](#page-2-0).

In addition, as shown in Figure S8 in the [SI](#page-7-0), 500 ppm of  $SO_2$ was added to the reaction gas at 250 °C to evaluate the  $SO_2$ resistance of the CeMo<sub>0.5</sub> $Zr_2O_x$  catalyst. The results showed that the  $NO<sub>x</sub>$  conversion was greatly declined from the initial 100% to 30%, which was greatly different from the effect of 100 ppm on the  $NO<sub>x</sub>$  conversion in Figure [2](#page-2-0)B, indicating that a higher concentration of  $SO_2$  would lead to a serious deactivation of the catalyst. However, in real applications, the concentration of  $SO<sub>2</sub>$  from diesel engine exhaust depends on the sulfur content of the diesel fuel. In recent years,  $SO_2$  in diesel engine exhaust is only tens of parts per million, which is much lower than 500 ppm.

In order to further investigate the influence of  $SO_2/H_2O$ treatment on the  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_x$  catalyst, the NH<sub>3</sub>-SCR activity as a function of the reaction temperature of  $CeMo_{0.5}Zr_2O_x$ catalysts treated in  $SO_2/H_2O$  for 48 h in Figure [2](#page-2-0) was retested, and the results are shown in Figure 3. Prior to the activity measurements of CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> catalysts treated in  $SO_2/H_2O$ 

Figure 3. NO<sub>x</sub> conversion in the NH<sub>3</sub>-SCR reaction as a function of the temperature over  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_x$  catalysts after treatment in  $\text{SO}_2/$  $H<sub>2</sub>O$  for 48 h. Reaction conditions:  $[NO] = [NH<sub>3</sub>] = 500$  ppm,  $[O<sub>2</sub>] =$ 5 vol %, and GHSV = 50000  $h^{-1}$ . .

for 48 h, the catalysts were calcined at 400 °C for 1 h to eliminate the ammonium sulfate deposited on the surface of the catalysts. Compared to the fresh  $CeMo_{0.5}Zr_2O_x$  catalyst, the SCR activity of the catalysts treated in  $SO<sub>2</sub>/H<sub>2</sub>O$  showed a slight decrease between 150 and 250 °C. However, the NO<sub>x</sub> conversion was still kept at more than 90% in the temperature range from 250 to 400 °C. Therefore, the CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> catalyst exhibits strong resistance to  $SO_2$  and  $H_2O$  poisoning, which can be used to remove  $NO<sub>x</sub>$  from diesel engine exhaust containing a certain amount of  $SO_2$  and  $H_2O$  vapor.

**3.3. Effect of GHSV.** The  $NO_x$  conversion over  $CeMo_{0.5}Zr_2O_x$  under different GHSVs is shown in Figure 4.

Figure 4. NO<sub>x</sub> conversion in the NH<sub>3</sub>-SCR reaction as a function of the temperature over the CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> catalyst under different GHSVs. Reaction conditions:  $[NO] = [NH<sub>3</sub>] = 500$  ppm and  $[O<sub>2</sub>] = 5$ vol %.

It can be seen that  $\mathrm{NO}_x$  conversion below 250  $^\circ\mathrm{C}$  decreased slightly when GHSV was increased from 50000 to 200000  $h^{-1}$ . . However, even at the highest GHSV of 200000  $h^{-1}$ , NO<sub>x</sub> conversion was still more than 90% in the temperature range from 250 to 400 °C. The effect of GHSV on the  $NO<sub>x</sub>$ conversion at high temperature was weaker than that at low temperature. These results indicated that the CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> catalyst is highly effective for the removal of  $NO<sub>x</sub>$  in a wide temperature range from 250 to 400 °C even when the reaction condition is harsh.

<span id="page-4-0"></span>**3.4. Thermal Stability Test.** In practical use, the  $NH<sub>3</sub>$ -SCR catalyst should also have good thermal stability in the long-term  $deNO<sub>x</sub>$  process. At the same time, to meet tougher emission standards of diesel engine exhaust, the diesel particulate filter (DPF) has to be used. The diesel exhaust gas temperature can reach above 700 °C during the regeneration process of the DPF system.<sup>27</sup> Therefore, the CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> catalysts were calcined at different temperatures (500, 550, 600, 650, 700, and 750  $^{\circ}$ C) for 8 h to test the thermal stability, and the results are illustrated in Figure 5A. As the calcination temperature

Figure 5. NO<sub>x</sub> conversion in the NH<sub>3</sub>-SCR reaction as a function of the temperature over  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_x$  (A) and  $\text{V}_2\text{O}_5-\text{WO}_3/\text{TiO}_2$  (B) catalysts calcined at different temperatures for 8 h. Reaction conditions:  $[NO] = [NH<sub>3</sub>] = 500$  ppm,  $[O<sub>2</sub>] = 5$  vol %, and GHSV  $=$  50000 h<sup>-1</sup>. .

increased from 500 to 700  $^{\circ}$ C, the NO<sub>x</sub> conversion below 250 °C showed a slight and monotonic decrease, while the conversion above 250 °C was quite similar. Further increasing the calcination temperature to 750 °C resulted in an obvious decrease of the  $NH<sub>3</sub>$ -SCR activity at both low and high temperatures, which might be caused by the decrease of the surface area and sintering of the active component. For comparison purposes, the SCR activity of commercial  $V_2O_5$ –  $WO_{3}/TiO_{2}$  catalysts with various  $V_{2}O_{5}$  contents calcined at 700 or 750 °C was also studied. As shown in Figure 5B, these catalysts show poor activity in the whole temperature range, which might be due to the decrease of the surface area, the anatase-to-rutile transition of  $TiO<sub>2</sub>$ , and the loss of vanadia.<sup>[15](#page-8-0)</sup> Compared to the commercial  $V_2O_5-WO_3/TiO_2$  catalyst, the  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_x$  catalyst exhibits much better high-temperature stability.

Moreover, as shown in Figure S9 in the [SI](#page-7-0), the CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> catalyst hydrothermally treated at 700 °C for 48 h still exhibited high NH<sub>3</sub>-SCR activity, over which more than 80% NO<sub>x</sub> conversion was obtained between 300 and 400 °C. Further increasing the aging temperature to 760 °C would resulted in an obvious diminution of the SCR activity, indicating that CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> could only be used below 700 °C. The hydrothermal stability of the CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> catalyst needs to be improved further in future studies.

3.5.  $N_2$  Physisorption and XRD Results. The specific surface area and BJH desorption pore volume of  $MoO<sub>3</sub>$ ,  $CeMo<sub>a</sub>Zr<sub>2</sub>O<sub>x</sub>$ , and  $CeMo<sub>0</sub> \times Zr<sub>2</sub>O<sub>x</sub>$  calcined at different temperatures are shown in Tables 1 and 2, respectively. As shown in

Table 1. BET Surface Area, Pore Volume, and  $CeO<sub>2</sub>$ Crystallite Size of MoO<sub>3</sub> and CeMo<sub>a</sub>Zr<sub>2</sub>O<sub>x</sub>

catalyst	$S_{\text{BET}}^a$ (m <sup>2</sup> /g)	pore volume <sup>b</sup> $\left(\text{cm}^3/\text{g}\right)$	$CeO2$ crystallite size <sup>c</sup> (nm)

Table 2. BET Surface Area, Pore Volume, and CeO<sub>2</sub> Crystallite Size of  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_x$  Calcined at Different Temperatures for 8 h

catalyst	$S_{\text{BET}}$ $(m^2/g)$	pore volume $\rm(cm^3/g)$	CeO <sub>2</sub> crystallite size (nm)
$CeMo0$ <sub>s</sub> $Zr2Or$ 500 $\degree$ C	77.8	0.038	12.1
$CeMo_{0.5}Zr_{2}O_{x}$ 550 $\degree$ C	75.8	0.040	12.1
$CeMo_{0.5}Zr_{2}O_{x}$ 600 °C	71.3	0.058	14.8
$CeMo_{0.5}Zr_{2}O_{x}$ 650 °C	47.7	0.070	15.9
$CeMo_{0.5}Zr_{2}O_{x}$ 700 °C	33.0	0.070	21.2
$CeMo_{0.5}Zr_2O_x$ - 750 °C	21.1	0.063	22.4

Table 1, the addition of a small amount of Mo  $(Mo:Ce = 0.1:1)$ to  $CeZr<sub>2</sub>O<sub>x</sub>$  showed a negligible effect on the surface area. However, when the molar ratio of Mo:Ce was more than 0.5:1, the surface area of the catalysts decreased obviously as the Mo loading increased because of the quite small surface area of MoO3. It was also reported that the addition of Mo could reduce the surface area of  $MoO<sub>3</sub>-CeO<sub>2</sub>$  catalysts, which were prepared by coprecipitation using urea as the precipitant.<sup>[28](#page-8-0)</sup> Meanwhile, the doping of Mo into  $CeZr<sub>2</sub>O<sub>x</sub>$  decreased the pore volume.

Table 2 shows the surface area and pore volume of  $CeMo_{0.5}Zr_2O_x$  calcined at different temperatures. It could be seen that increasing the calcination temperature from 500 to 750 °C resulted in a decrease of the surface area from 77.8 to 21.1  $\mathrm{m}^2/\mathrm{g}$ , while the pore volume increased gradually. The decrease of the surface area and the sintering of the active component at high calcination temperatures might be responsible for the decrease of the  $NO<sub>x</sub>$  conversion at low temperatures.<sup>[29](#page-8-0)</sup>

The XRD results of the catalysts with different Mo loadings are summarized in Figure [6A](#page-5-0). The reflections provided typical diffraction patterns for the CeO<sub>2</sub> cubic phase (JCPDS 34-0394) and the  $ZrO<sub>2</sub>$  tetragonal phase (JCPDS 50-1089). No diffraction peaks attributed to Mo species were detected in the XRD patterns, implying that Mo species were finely dispersed on the surface of the catalysts or existed as amorphous species. Furthermore, as shown in Table 1, the

<span id="page-5-0"></span>

Figure 6. Powder XRD of CeMo<sub>a</sub>Zr<sub>2</sub>O<sub>x</sub> catalysts with different Mo loadings (A) and  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_x$  catalysts calcined at different temperatures for 8 h (B).

average crystallite size of  $CeO<sub>2</sub>$  calculated by the Scherrer equation decreased slightly as the Mo content increased. As presented in Figure 6B, the XRD patterns of  $\text{CeMo}_0$ ,  $\text{Zr}_2\text{O}_x$ samples calcined at various temperatures from 500 to 750 °C for 8 h showed typical diffraction peaks for the cubic  $CeO<sub>2</sub>$  and tetragonal  $ZrO<sub>2</sub>$  phases, and no diffraction peaks for Mo species were detected. With increasing calcination temperature, the intensities of all of the diffraction peaks increased slightly and the  $CeO<sub>2</sub>$  average crystallite size increased from 12.1 to 22.4 nm (Table [2\)](#page-4-0). However, after high-temperature calcination, the positions of the diffraction peaks stayed the same, indicating that changes of the crystallite phases of  $CeO<sub>2</sub>$  and  $ZrO<sub>2</sub>$  did not occur in this process.

3.6. Raman Spectra. Visible Raman spectra were also applied to characterize the  $\text{CeMo}_{a}\text{Zr}_{2}\text{O}_{x}$  catalysts, and the results are presented in Figure 7.  $CeZr<sub>2</sub>O<sub>x</sub>$  showed an obvious band at 463 cm<sup>−</sup><sup>1</sup> and three weak peaks at about 630, 315, and

Figure 7. Visible Raman spectra of the  $CeMo<sub>a</sub>Zr<sub>2</sub>O<sub>x</sub>$  catalysts.

270 cm<sup>-1</sup>. The band at 463 cm<sup>-1</sup> was due to the Raman-active  $F_{2g}$  mode of the CeO<sub>2</sub> fluorite structure.<sup>[30](#page-8-0)</sup> The band at 630  $\text{cm}^{-1}$  could be a consequence of the lattice contraction brought about by Zr ion insertion.[9](#page-8-0) The bands at 315 and 270 cm<sup>−</sup><sup>1</sup> could be assigned to the Zr phase  $(t-ZrO<sub>2</sub>)$ .<sup>31–[33](#page-8-0)</sup> With an increase of the Mo content, the Raman spectral intensity of  $CeO<sub>2</sub>$  decreased significantly, which proved that the introduction of Mo inhibited growth of the  $CeO<sub>2</sub>$  particle size.<sup>[25](#page-8-0)</sup> These analytical results are in good accordance with the conclusion drawn from XRD results. In combination with the XRD and Raman results, it could be concluded that Mo species were mainly present in a highly dispersed state and the addition of Mo resulted in a decrease of the  $CeO<sub>2</sub>$  crystallite size. However, the  $CeO<sub>2</sub>$  crystallite size was not the only factor leading to the discrepancy of the catalytic activity between different catalysts.

**3.7.**  $H_2$ -TPR.  $H_2$ -TPR experiments were conducted to investigate the redox ability of the catalysts, and the results are shown in Figure 8. For the  $CeZr<sub>2</sub>O<sub>x</sub>$  catalyst, the reduction

Figure 8. H<sub>2</sub>-TPR profiles of the CeMo<sub>a</sub> $Zr_2O_x$  catalysts.

peak at about 510 °C was attributed to the reduction of surface  $Ce^{4+}$  to  $Ce^{3+25,34}$  $Ce^{3+25,34}$  $Ce^{3+25,34}$  After the introduction of Mo to  $CeZr_2O_{x}$ , the reduction peak of surface  $Ce^{4+}$  moved to lower temperatures, which indicated that the mobility of surface O was greatly improved because of the strong synergetic effect among Zr, Ce, and Mo species. It is believed that the synergetic effect gave rise to severe structural distortion and abundant O defects.<sup>[16,35](#page-8-0)</sup> The O defects facilitated O diffusion from the subsurface layers and might progressively proceed deeper into the bulk.<sup>[36](#page-8-0),[37](#page-8-0)</sup> All of the above features were beneficial for the SCR activity. In addition, it was also reported that the mobility of surface O on the  $CeMoAIO_x$  catalyst was enhanced by Mo addition.<sup>[38](#page-8-0)</sup>  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_x$  exhibited the lowest reduction temperature at 448 °C, which was in harmony with its highest SCR activity. However, upon a further increase of the Mo/Ce molar ratios from 0.5 to 1.5, the reduction peaks attributed to the overlap of Ce and Mo species shifted to higher temperatures, which might be caused by the coverage of Mo species. These results indicate that the stronger oxidation reduction ability of  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_{x}$ benefits the excellent SCR reaction performance.

**3.8. In Situ DRIFTS Studies.** 3.8.1.  $NH<sub>3</sub>$  Adsorption. In situ DRIFTS spectra of NH<sub>3</sub> adsorption at 200 °C were measured to examine the change of acidity on the catalysts after Mo addition, and the results are shown in Figure [9](#page-6-0)A. After exposure to  $NH<sub>3</sub>$ , the catalysts were covered by several kinds of  $NH<sub>3</sub>$ species. The bands at 1668 cm<sup>-1</sup> and 1425, 1440, and 1414 cm<sup>−</sup><sup>1</sup> were assigned to symmetric and asymmetric bending

<span id="page-6-0"></span>

Figure 9. In situ DRIFTS of NH<sub>3</sub> adsorption (A) and NO + O<sub>2</sub> adsorption (B) at 200 °C on the CeMo<sub>a</sub>Zr<sub>2</sub>O<sub>x</sub> series of catalysts.

Figure 10. In situ DRIFTS of NO + O<sub>2</sub> reacted with preadsorbed NH<sub>3</sub> species (A) and NH<sub>3</sub> reacted with preadsorbed NO<sub>x</sub> species (B) at 200 °C on the CeMo $_{0.5}Zr_2O_x$  catalyst.

vibrations, respectively, of  $NH_4^+$  species on Brønsted acid sites.<sup>[5](#page-7-0),[22,39](#page-8-0)−[41](#page-8-0)</sup> The bands at 1605 and 1595 cm<sup>-1</sup> and at 1232 and 1190  $cm^{-1}$  were attributed to asymmetric and symmetric bending vibrations, respectively, of the N−H bonds in coordinated NH<sub>3</sub> linked to Lewis acid sites, respectively.<sup>[42](#page-8-0)[,43](#page-9-0)</sup> The bands at 3354 and 3264 cm<sup>-1</sup> ascribed to N−H stretching modes of coordinated  $NH_3$  were also observed.<sup>[23](#page-8-0)</sup> Some negative bands around 3700 cm<sup>-1</sup> were also found that could be assigned to hydroxyl consumption due to interaction between the hydroxyl groups and  $\rm NH_3$  to form  $\rm NH_4.^{4.5,35}$  $\rm NH_4.^{4.5,35}$  $\rm NH_4.^{4.5,35}$  $\rm NH_4.^{4.5,35}$ .

Compared to  $CeZr<sub>2</sub>O<sub>x</sub>$ , the addition of Mo enhanced the band intensities of adsorbed  $\mathrm{NH_4}^+$  greatly. This meant that the introduction of Mo resulted in more Brønsted acid sites on the catalyst surface, and similar results were also found on  $CeO<sub>2</sub>−$  $MoO<sub>3</sub>$  catalysts in the published literature.<sup>[25,28](#page-8-0)</sup> For coordinated NH3 bound to Lewis acid sites, the band intensity first had an obvious increase and then showed a decrease when the molar ratio of Mo:Ce was higher than  $0.5:1$ . In addition, the NH<sub>3</sub>-TPD results indicated that the total amount of  $NH<sub>3</sub>$  adsorbed on CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> was higher than that on the CeZr<sub>2</sub>O<sub>x</sub> catalyst; see Figure S10A in the [SI](#page-7-0). The band intensity due to Lewis acid sites over  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_x$  was the highest among the series of

catalysts, which was in good accordance with the results of the SCR activity. Although the intensity of adsorbed  $NH_4^+$  over CeMo<sub>1.0</sub>Zr<sub>2</sub>O<sub>x</sub> was stronger than that over CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub>,  $CeMo<sub>05</sub>Zr<sub>2</sub>O<sub>x</sub>$  exhibited higher band intensity attributed to coordinated  $NH<sub>3</sub>$  adsorption. It can be concluded that the Lewis acid sites over the CeMo<sub>0.5</sub> $Zr_2O_r$  catalyst are responsible for its highest SCR activity. Peng et al. investigated the structure activity relationship of the  $MoO<sub>3</sub>-CeO<sub>2</sub>$  catalyst for  $NH<sub>3</sub>-SCR$  of  $NO<sub>x</sub>$  and found that the Lewis acid sites could be involved in the reaction even more rapidly than the Brønsted acid sites.[28](#page-8-0)

3.8.2. NO +  $O_2$  Adsorption. Figure 9B presents the in situ DRIFTS results of NO<sub>x</sub> adsorption at 200 °C. After NO +  $O_2$ adsorption and  $N_2$  purge, several distinct bands attributed to monodentate nitrate (1506 and 1276 cm<sup>-1</sup>), bidentate nitrate (1593 and 1568 cm<sup>−</sup><sup>1</sup> ), and bridging nitrate (1615, 1620, 1241, and 1217 cm<sup>−</sup><sup>1</sup> ) appeared.[39,](#page-8-0)[44](#page-9-0)−[46](#page-9-0) With increasing Mo addition content, the bands due to adsorbed nitrate species showed an obvious decrease in intensity, and only bridging nitrate species were observed on the CeMo<sub>1.5</sub>Zr<sub>2</sub>O<sub>x</sub> catalyst. It is concluded that the addition of Mo significantly limits the adsorption of nitrate species, which could also be confirmed by the results <span id="page-7-0"></span>drawn from NO-TPD in Figure S10B in the SI. It is believed that the introduction of  $MoO<sub>3</sub>$  resulted in the formation of more acid sites accompanied by the reduction of basic sites where nitrate adsorbed.<sup>[22](#page-8-0)</sup> The inhibitory effect of Mo on the adsorption of nitrate species has also been reported by other researchers on the  $M_0O_3$ -CeO<sub>2</sub>/TiO<sub>2</sub><sup>[22](#page-8-0)</sup> and CeMo<sub>0.5</sub>AlO<sub>x</sub><sup>[38](#page-8-0)</sup> catalysts for the NH<sub>3</sub>-SCR process.

3.8.3. Reaction between NO +  $O<sub>2</sub>$  and Adsorbed NH<sub>3</sub> Species. To investigate the reactivity of adsorbed  $NH<sub>3</sub>$  species in the SCR reaction on the CeMo<sub>0.5</sub> $Zr_2O_x$  catalyst, in situ DRIFTS of the reaction between preadsorbed  $NH<sub>3</sub>$  and NO +  $O_2$  at 200 °C was recorded as a function of time (Figure [10A](#page-6-0)). After the introduction of  $NO + O<sub>2</sub>$ , the bands ascribed to ionic  $NH_4^+$  (1668 and 1425 cm<sup>-1</sup>) and coordinated NH<sub>3</sub> (3354, 3264, 1605, and 1232  $\text{cm}^{-1}$ ) showed an apparent decrease in intensity, and all of the bands were replaced by nitrate species after 5 min. This indicates that both coordinated  $NH<sub>3</sub>$  and ionic  $NH_4^+$  on the  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_x$  catalyst could react as reducing agents to reduce  $NO<sub>x</sub>$ . Although coordinated  $NH<sub>3</sub>$  over the  $CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub>$  catalyst was responsible for its highest SCR activity, ionic  $NH_4^+$  could also be involved in the SCR reaction. It could be concluded that the addition of Mo to  $CeZr<sub>2</sub>O<sub>x</sub>$ resulted in more coordinated  $NH_3$  and ionic  $NH_4^+$ , both of which could participate in the  $NH<sub>3</sub>$ -SCR reaction.

3.8.4. Reaction between NH<sub>3</sub> and Adsorbed NO<sub>x</sub> Species. The reactivity of absorbed  $NO<sub>x</sub>$  species in the SCR reaction on the CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> catalyst was also investigated by the in situ DRIFTS of the reaction between preadsorbed  $NO<sub>x</sub>$  and  $NH<sub>3</sub>$  at 200 °C, and the results are shown in Figure [10B](#page-6-0). After exposure to  $NO + O<sub>2</sub>$ , the catalyst was mainly covered by bidentate nitrate (1568 cm<sup>−</sup><sup>1</sup> ) and bridging nitrate (1620 and 1217 cm<sup>-1</sup>). When NH<sub>3</sub> was introduced, the bridging nitrate was greatly decreased and disappeared in 5 min, while the bidentate nitrate did not show an obvious decrease. At the same time, the bands attributed to ionic  $NH_4^+$  (1668 and 1425 cm<sup>-1</sup>) and coordinated NH<sub>3</sub> (3354, 3264, 1605, and 1232  $\text{cm}^{-1}$ ) were observed after 5 min. The results indicate that bridging nitrate rather than bidentate nitrate can react with NH<sub>3</sub>. Although the addition of Mo inhibited the adsorption of nitrate species on the surface, the reaction between adsorbed nitrate species and  $NH_3$  still played a significant role in the reduction of  $NO<sub>x</sub>$ . Judging from Figure [9](#page-6-0)B, the amount of nitrate species on  $CeMo<sub>0.1</sub>Zr<sub>2</sub>O<sub>x</sub>$  was higher than that on other Mo-containing catalysts, indicating that  $\text{CeMo}_{0.1}\text{Zr}_2\text{O}_x$  should be an excellent catalyst for the SCR reaction. However, the lack of enough NH<sub>3</sub> species on the surface of  $CeMo_{0.1}Zr_2O_x$  (Figure [9](#page-6-0)A) lowered SCR conversion, as seen in Figure [1.](#page-2-0) The adsorption amounts of coordinated  $NH<sub>3</sub>$  and nitrate species on CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> were both higher than that on CeMo<sub>1.0</sub>Zr<sub>2</sub>O<sub>x</sub> or CeMo<sub>1.5</sub>Zr<sub>2</sub>O<sub>x</sub>. It is believed that the adsorption of NH<sub>3</sub> and  $NO<sub>x</sub>$  was considered to be essential in the  $NH<sub>3</sub>$ -SCR reaction at low temperatures. Liu et al. investigated the promoting effect of  $MoO<sub>3</sub>$  on the NH<sub>3</sub>-SCR activity over the CeO<sub>2</sub>/TiO<sub>2</sub> catalyst and believed that the unsaturated Mo resulted in more acid sites, which was favorable for the adsorption of  $NH<sub>3</sub>$ , thus improving the low-temperature activity.<sup>[22](#page-8-0)</sup> Nitro and nitrate groups were beneficial to promote the SCR process at low temperatures over an F-doped  $CeO<sub>2</sub>$ -TiO<sub>2</sub> catalyst.<sup>[47](#page-9-0)</sup> In addition, the results in Figure [10](#page-6-0) show that both adsorbed  $\mathrm{NH}_3$  species (coordinated  $\mathrm{NH}_3$ , ionic  $\mathrm{NH}_4^+$ ) and adsorbed bridging nitrate species were active in the  $NH<sub>3</sub>-SCR$  action. Therefore, it was reasonable to conclude that the high

adsorption amounts of  $NH<sub>3</sub>$  and nitrate species were favorable for the high activity of the CeMo<sub>0.5</sub> $Zr_2O_x$  catalyst.

#### 4. CONCLUSIONS

A novel Mo-promoted Ce−Zr catalyst prepared by a homogeneous precipitation method was used for NH<sub>3</sub>-SCR of NO<sub>x</sub>. The CeMo<sub>0.5</sub>Zr<sub>2</sub>O<sub>x</sub> catalyst with a Mo:Ce molar ratio of 0.5:1 showed high SCR activity,  $SO_2/H_2O$  durability, and thermal stability under test conditions. Characterization results indicated that Mo addition inhibited growth of the  $CeO<sub>2</sub>$ particle size, improved the redox ability, and increased the amount of surface acidity, especially the Lewis acidity. Coordinated  $\mathrm{NH}_3$  and ionic  $\mathrm{NH_4^+}$  species together with bridging nitrate were active over the  $\text{CeMo}_{0.5}\text{Zr}_2\text{O}_x$  catalyst during the  $NH<sub>3</sub>-SCR$  reaction. All of the features above are responsible for the excellent NH<sub>3</sub>-SCR performance.
